## 1 Inductive sets

Induction is an important concept in the theory of programming language. We have already seen it used to define language syntax, and to define the small-step operational semantics for the arithmetic language.

An inductively defined set $A$ is a set that is built using a set of axioms and inductive (inference) rules. Axioms of the form

$$
\overline{a \in A}
$$

indicate that $a$ is in the set $A$. Inductive rules

\[

\]

indicate that if $a_{1}, \ldots, a_{n}$ are all elements of $A$, then $a$ is also an element of $A$.
The set $A$ is the set of all elements that can be inferred to belong to $A$ using a (finite) number of applications of these rules, starting only from axioms. In other words, for each element $a$ of $A$, we must be able to construct a finite proof tree whose final conclusion is $a \in A$.

Example 1. The language of a grammar is an inductive set. For instance, the set of arithmetic expressions can be described with 2 axioms, and 3 inductive rules:

$$
\begin{gathered}
\operatorname{VAR} \frac{}{x \in \operatorname{Exp}} x \in \operatorname{Var} \quad \operatorname{INT} \frac{}{n \in \operatorname{Exp}} n \in \operatorname{Int} \\
\operatorname{ADD} \frac{e_{1} \in \operatorname{Exp} \quad e_{2} \in \mathbf{E x p}}{e_{1}+e_{2} \in \operatorname{Exp}} \quad \operatorname{MUL} \frac{e_{1} \in \operatorname{Exp} \quad e_{2} \in \operatorname{Exp}}{e_{1} \times e_{2} \in \operatorname{Exp}} \quad \text { Ass } \frac{e_{1} \in \operatorname{Exp} \quad e_{2} \in \operatorname{Exp}}{x:=e_{1} ; e_{2} \in \operatorname{Exp}} x \in \operatorname{Var}
\end{gathered}
$$

This is equivalent to the grammar $e::=x|n| e_{1}+e_{2}\left|e_{1} \times e_{2}\right| x:=e_{1} ; e_{2}$.
To show that (foo +3 ) $\times$ bar is an element of the set Exp, it suffices to show that foo +3 and bar are in the set Exp, since the inference rule MUL can be used, with $e_{1} \equiv$ foo +3 and $e_{2} \equiv$ foo, and, since if the premises foo $+3 \in \operatorname{Exp}$ and bar $\in \operatorname{Exp}$ are true, then the conclusion (foo +3 ) $\times$ bar $\in \operatorname{Exp}$ is true.

Similarly, we can use rule ADD to show that if foo $\in \operatorname{Exp}$ and $3 \in \operatorname{Exp}$, then $($ foo +3$) \in \operatorname{Exp}$. We can use axiom VAR (twice) to show that foo $\in \operatorname{Exp}$ and bar $\in \operatorname{Exp}$ and rule INT to show that $3 \in \operatorname{Exp}$. We can put these all together into a derivation whose conclusion is $(\mathrm{foo}+3) \times$ bar $\in \operatorname{Exp}$ :

Example 2. The natural numbers can be inductively defined:

$$
\overline{0 \in \mathbb{N}} \quad \frac{n \in \mathbb{N}}{\operatorname{succ}(n) \in \mathbb{N}}
$$

where $\operatorname{succ}(n)$ is the successor of $n$.

Example 3. The small-step evaluation relation $\longrightarrow$ is an inductively defined set. The definition of this set is given by the semantic rules.
Example 4. The transitive, reflexive closure $\longrightarrow^{*}$ (i.e., the multi-step evaluation relation) can be inductively defined:

$$
\frac{}{\langle e, \sigma\rangle \longrightarrow^{*}\langle e, \sigma\rangle} \quad \frac{\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle \quad\left\langle e^{\prime}, \sigma^{\prime}\right\rangle \longrightarrow^{*}\left\langle e^{\prime \prime}, \sigma^{\prime \prime}\right\rangle}{\langle e, \sigma\rangle \longrightarrow^{*}\left\langle e^{\prime \prime}, \sigma^{\prime \prime}\right\rangle}
$$

## 2 Inductive proofs

We can prove facts about elements of an inductive set using an inductive reasoning that follows the structure of the set definition.

### 2.1 Mathematical induction

You have probably seen proofs by induction over the natural numbers, called mathematical induction. In such proofs, we typically want to prove that some property $P$ holds for all natural numbers, that is, $\forall n \in \mathbb{N}$. $P(n)$. A proof by induction works by first proving that $P(0)$ holds, and then proving for all $m \in \mathbb{N}$, if $P(m)$ then $P(m+1)$. The inductive reasoning principle of mathematical induction can be stated as follows:

```
For any property P,
If
- \(P(0)\) holds
- For all natural numbers \(n\), if \(P(n)\) holds then \(P(n+1)\) holds
then
```

for all natural numbers $k, P(k)$ holds.
Here, $P$ is the property that we are proving by induction. The assertion that $P(0)$ is the basis of the induction (also called the base case). Establishing that $P(m) \Longrightarrow P(m+1)$ is called inductive step, or the inductive case. While proving the inductive step, the assumption that $P(m)$ holds is called the inductive hypothesis.

This inductive reasoning principle gives us a technique to prove that a property holds for all natural numbers, which is an infinite set. Why is the inductive reasoning principle for natural numbers sound? That is, why does it work? One intuition is that for any natural number $k$ you choose, $k$ is either zero, or the result of applying the successor operation a finite number of times to zero. That is, we have a finite proof tree that $k$ is a natural number, using the inference rules given in Example 2 of Lecture 2. Given this proof tree, the leaf of this tree is that $0 \in \mathbb{N}$. We know that $P(0)$ holds. Moreover, since we have for all natural numbers $n$, if $P(n)$ holds then $P(n+1)$ holds, and we have $P(0)$, we also have $P(1)$. Since we have $P(1)$, we also have $P(2)$, and so on. That is, for each node of the proof tree, we are showing that the property holds of that node. Eventually we will reach the root of the tree, that $k \in N$, and we will have $P(k)$.

### 2.2 Induction on inductively-defined sets

For every inductively defined set, we have a corresponding inductive reasoning principle. The template for this inductive reasoning principle, for an inductively defined set $A$, is as follows.

For any property $P$,
If

- Base cases: For each axiom

$$
a \in A
$$

$P(a)$ holds.

- Inductive cases: For each inference rule

$$
\frac{a_{1} \in A \quad \ldots \quad a_{n} \in A}{a \in A},
$$

if $P\left(a_{1}\right)$ and $\ldots$ and $P\left(a_{n}\right)$ then $P(a)$.
then
for all $a \in A, P(a)$ holds.
Again, $P$ is the property that we are proving by induction. Each axiom for the inductively defined set (i.e., each inference rule with no premises) is a base case for the induction. Each inductive inference rules (i.e., inference rules with one or more premises) are the inductive cases. When proving an inductive case (i.e., if $P\left(a_{1}\right)$ and $\ldots$ and $P\left(a_{n}\right)$ then $P(a)$ ), the assumption that $P\left(a_{1}\right)$ and $\ldots$ and $P\left(a_{n}\right)$ are true is the inductive hypothesis.

If the set $A$ is the set of natural numbers (see Example 2 above), then the requirements given above for proving that $P$ holds for all elements of $A$ are equivalent to mathematical induction.

If $A$ describes a syntactic set, then we refer to induction following the requirements above as structural induction. If $A$ is an operational semantics relation (such as the small-step operational semantics relation $\longrightarrow)$ then such induction is called induction on derivations. We will see examples of structural induction and induction on derivations throughout the course.

The intuition for why the inductive reasoning principle works is that same as the intuition for why mathematical induction works, i.e., for why the inductive reasoning principle for natural numbers works.

### 2.3 Example inductive reasoning principles

Let's consider a specific inductively defined set, and consider the inductive reasoning principle for that set: the set of arithmetic expressions AExp, inductively defined by the grammar

$$
e::=x|n| e_{1}+e_{2}\left|e_{1} \times e_{2}\right| x:=e_{1} ; e_{2}
$$

Here is the inductive reasoning principle for the set AExp.
For any property $P$,
If

- For all variables $x, P(x)$ holds.
- For all integers $n, P(n)$ holds.
- For all $e_{1} \in \mathbf{A E x p}$ and $e_{2} \in \mathbf{A E x p}$, if $P\left(e_{1}\right)$ and $P\left(e_{2}\right)$ then $P\left(e_{1}+e_{2}\right)$ holds.
- For all $e_{1} \in \mathbf{A E x p}$ and $e_{2} \in \mathbf{A E x p}$, if $P\left(e_{1}\right)$ and $P\left(e_{2}\right)$ then $P\left(e_{1} \times e_{2}\right)$ holds.
- For all variables $x$ and $e_{1} \in \operatorname{AExp}$ and $e_{2} \in \operatorname{AExp}$, if $P\left(e_{1}\right)$ and $P\left(e_{2}\right)$ then $P\left(x:=e_{1} ; e_{2}\right)$ holds.
then
for all $e \in \operatorname{AExp}, P(e)$ holds.
Here is the inductive reasoning principle for the small step relation on arithmetic expressions, i.e., for the set $\longrightarrow$.

For any property $P$,
If

- VAR: For all variables $x$, stores $\sigma$ and integers $n$ such that $\sigma(x)=n, P(\langle x, \sigma\rangle \longrightarrow\langle n, \sigma\rangle)$ holds.
- ADD: For all integers $n, m, p$ such that $p=n+m$, and stores $\sigma, P(\langle n+m, \sigma\rangle \longrightarrow\langle p, \sigma\rangle)$ holds.
- MUL: For all integers $n, m, p$ such that $p=n \times m$, and stores $\sigma, P(\langle n \times m, \sigma\rangle \longrightarrow\langle p, \sigma\rangle)$ holds.
- ASG: For all variables $x$, integers $n$ and expressions $e \in \operatorname{AExp}, P(\langle x:=n ; e, \sigma\rangle \longrightarrow$ $\langle e, \sigma[x \mapsto n]\rangle)$ holds.
- LADD: For all expressions $e_{1}, e_{2}, e_{1}^{\prime} \in$ AExp and stores $\sigma$ and $\sigma^{\prime}$, if $P\left(\left\langle e_{1}, \sigma\right\rangle \longrightarrow\left\langle e_{1}^{\prime}, \sigma^{\prime}\right\rangle\right)$ holds then $P\left(\left\langle e_{1}+e_{2}, \sigma\right\rangle \longrightarrow\left\langle e_{1}^{\prime}+e_{2}, \sigma^{\prime}\right\rangle\right)$ holds.
- RADD: For all integers $n$, expressions $e_{2}, e_{2}^{\prime} \in$ AExp and stores $\sigma$ and $\sigma^{\prime}$, if $P\left(\left\langle e_{2}, \sigma\right\rangle \longrightarrow\right.$ $\left.\left\langle e_{2}^{\prime}, \sigma^{\prime}\right\rangle\right)$ holds then $P\left(\left\langle n+e_{2}, \sigma\right\rangle \longrightarrow\left\langle n+e_{2}^{\prime}, \sigma^{\prime}\right\rangle\right)$ holds.
- LMUL: For all expressions $e_{1}, e_{2}, e_{1}^{\prime} \in$ AExp and stores $\sigma$ and $\sigma^{\prime}$, if $P\left(\left\langle e_{1}, \sigma\right\rangle \longrightarrow\left\langle e_{1}^{\prime}, \sigma^{\prime}\right\rangle\right)$ holds then $P\left(\left\langle e_{1} \times e_{2}, \sigma\right\rangle \longrightarrow\left\langle e_{1}^{\prime} \times e_{2}, \sigma^{\prime}\right\rangle\right)$ holds.
- RMUL: For all integers $n$, expressions $e_{2}, e_{2}^{\prime} \in \operatorname{AExp}$ and stores $\sigma$ and $\sigma^{\prime}$, if $P\left(\left\langle e_{2}, \sigma\right\rangle \longrightarrow\right.$ $\left.\left\langle e_{2}^{\prime}, \sigma^{\prime}\right\rangle\right)$ holds then $P\left(\left\langle n \times e_{2}, \sigma\right\rangle \longrightarrow\left\langle n \times e_{2}^{\prime}, \sigma^{\prime}\right\rangle\right)$ holds.
- AsG1: For all variables $x$, expressions $e_{1}, e_{2}, e_{1}^{\prime} \in$ AExp and stores $\sigma$ and $\sigma^{\prime}$, if $P\left(\left\langle e_{1}, \sigma\right\rangle \longrightarrow\right.$ $\left.\left\langle e_{1}^{\prime}, \sigma^{\prime}\right\rangle\right)$ holds then $P\left(\left\langle x:=e_{1} ; e_{2}, \sigma\right\rangle \longrightarrow\left\langle x:=e_{1}^{\prime} ; e_{2}, \sigma^{\prime}\right\rangle\right)$ holds.

## then

for all $\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle, P\left(\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle\right)$ holds.
Note that there is one case for each inference rule: 4 axioms (VAR, ADD, MUL and ASG) and 5 inductive rules (LADD, RADD, LMUL, RMUL, AsG1).

The inductive reasoning principles give us a technique for showing that a property holds of every element in an inductively defined set. Let's consider some examples. Make sure you understand how the appropriate inductive reasoning principle is being used in each of these examples.

### 2.4 Example: Proving progress

Let's consider the progress property defined above, and repeated here:
Progress: For each store $\sigma$ and expression $e$ that is not an integer, there exists a possible transition for $\langle e, \sigma\rangle$ :

$$
\forall e \in \operatorname{Exp} . \forall \sigma \in \text { Store. either } e \in \text { Int or } \exists e^{\prime}, \sigma^{\prime} .\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle
$$

Let's rephrase this property as: for all expressions $e, P(e)$ holds, where:

$$
P(e)=\forall \sigma .(e \in \mathbf{I n t}) \vee\left(\exists e^{\prime}, \sigma^{\prime} .\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle\right)
$$

The idea is to build a proof that follows the inductive structure in the grammar of expressions:

$$
e::=x|n| e_{1}+e_{2}\left|e_{1} \times e_{2}\right| x:=e_{1} ; e_{2} .
$$

This is called "structural induction on the expressions $e^{\text {". We must examine each case in the grammar }}$ and show that $P(e)$ holds for that case. Since the grammar productions $e=e_{1}+e_{2}$ and $e=e_{1} \times e_{2}$ and $e=x:=e_{1} ; e_{2}$ are inductive definitions of expressions, they are inductive steps in the proof; the other two cases $e=x$ and $e=n$ are the basis of induction. The proof goes as follows:

We will prove by structural induction on expressions Exp that for all expressions $e \in \operatorname{Exp}$ we have

$$
P(e)=\forall \sigma .(e \in \mathbf{I n t}) \vee\left(\exists e^{\prime}, \sigma^{\prime} .\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle\right)
$$

Consider the possible cases for $e$.

- Case $e=x$. By the VAR axiom, we can evaluate $\langle x, \sigma\rangle$ in any state: $\langle x, \sigma\rangle \longrightarrow\langle n, \sigma\rangle$, where $n=\sigma(x)$. So $e^{\prime}=n$ is a witness that there exists $e^{\prime}$ such that $\langle x, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma\right\rangle$, and $P(x)$ holds.
- Case $e=n$. Then $e \in$ Int, so $P(n)$ trivially holds.
- Case $e=e_{1}+e_{2}$. This is an inductive step. The inductive hypothesis is that $P$ holds for subexpressions $e_{1}$ and $e_{2}$. We need to show that $P$ holds for $e$. In other words, we want to show that $P\left(e_{1}\right)$ and $P\left(e_{2}\right)$ implies $P(e)$. Let's expand these properties. We know that the following hold:

$$
\begin{aligned}
& P\left(e_{1}\right)=\forall \sigma .\left(e_{1} \in \text { Int }\right) \vee\left(\exists e^{\prime}, \sigma^{\prime} .\left\langle e_{1}, \sigma\right\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle\right) \\
& P\left(e_{2}\right)=\forall \sigma .\left(e_{2} \in \text { Int }\right) \vee\left(\exists e^{\prime}, \sigma^{\prime} .\left\langle e_{2}, \sigma\right\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle\right)
\end{aligned}
$$

and we want to show:

$$
P(e)=\forall \sigma .(e \in \mathbf{I n t}) \vee\left(\exists e^{\prime}, \sigma^{\prime} .\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle\right)
$$

We must inspect several subcases.
First, if both $e_{1}$ and $e_{2}$ are integer constants, say $e_{1}=n_{1}$ and $e_{2}=n_{2}$, then by rule ADD we know that the transition $\left\langle n_{1}+n_{2}, \sigma\right\rangle \longrightarrow\langle n, \sigma\rangle$ is valid, where $n$ is the sum of $n_{1}$ and $n_{2}$. Hence, $P(e)=P\left(n_{1}+n_{2}\right)$ holds (with witness $e^{\prime}=n$ ).
Second, if $e_{1}$ is not an integer constant, then by the inductive hypothesis $P\left(e_{1}\right)$ we know that $\left\langle e_{1}, \sigma\right\rangle \longrightarrow$ $\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$ for some $e^{\prime}$ and $\sigma^{\prime}$. We can then use rule LADD to conclude $\left\langle e_{1}+e_{2}, \sigma\right\rangle \longrightarrow\left\langle e^{\prime}+e_{2}, \sigma^{\prime}\right\rangle$, so $P(e)=P\left(e_{1}+e_{2}\right)$ holds.
Third, if $e_{1}$ is an integer constant, say $e_{1}=n_{1}$, but $e_{2}$ is not, then by the inductive hypothesis $P\left(e_{2}\right)$ we know that $\left\langle e_{2}, \sigma\right\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$ for some $e^{\prime}$ and $\sigma^{\prime}$. We can then use rule RADD to conclude $\left\langle n_{1}+\right.$ $\left.e_{2}, \sigma\right\rangle \longrightarrow\left\langle n_{1}+e^{\prime}, \sigma^{\prime}\right\rangle$, so $P(e)=P\left(n_{1}+e_{2}\right)$ holds.

- Case $e=e_{1} \times e_{2}$ and case $e=x:=e_{1} ; e_{2}$. These are also inductive cases, and their proofs are similar to the previous case. [Note that if you were writing this proof out for a homework, you should write these cases out in full.]

### 2.5 A recipe for inductive proofs

In this class, you will be asked to write inductive proofs. Until you are used to doing them, inductive proofs can be difficult. Here is a recipe that you should follow when writing inductive proofs. Note that this recipe was followed above.

1. State what you are inducting over. In the example above, we are doing structural induction on the expressions $e$.
2. State the property $P$ that you are proving by induction. (Sometimes, as in the proof above the property $P$ will be essentially identical to the theorem/lemma/property that you are proving; other times the property we prove by induction will need to be stronger than theorem/lemma/property you are proving in order to get the different cases to go through.)
3. Make sure you know the inductive reasoning principle for the set you are inducting on.
4. Go through each case. For each case, don't be afraid to be verbose, spelling out explicitly how the meta-variables in an inference rule are instantiated in this case.

### 2.6 Example: the store changes incremental

Let's see another example of an inductive proof, this time doing an induction on the derivation of the small step operational semantics relation. The property we will prove is that for all expressions $e$ and stores $\sigma$, if $\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$ then either $\sigma=\sigma^{\prime}$ or there is some variable $x$ and integer $n$ such that $\sigma^{\prime}=\sigma[x \mapsto n]$. That is, in one small step, either the new store is identical to the old store, or is the result of updating a single program variable.

Theorem 1. For all expressions $e$ and stores $\sigma$, if $\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$ then either $\sigma=\sigma^{\prime}$ or there is some variable $x$ and integer $n$ such that $\sigma^{\prime}=\sigma[x \mapsto n]$.

Proof of Theorem 1. We proceed by induction on the derivation of $\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$. Suppose we have $e$, $\sigma, e^{\prime}$ and $\sigma^{\prime}$ such that $\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$. The property $P$ that we will prove of $e, \sigma, e^{\prime}$ and $\sigma^{\prime}$, which we will write as $P\left(\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle\right)$, is that either $\sigma=\sigma^{\prime}$ or there is some variable $x$ and integer $n$ such that $\sigma^{\prime}=\sigma[x \mapsto n]:$

$$
P\left(\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle\right) \triangleq \sigma=\sigma^{\prime} \vee\left(\exists x \in \mathbf{V a r}, n \in \text { Int. } \sigma^{\prime}=\sigma[x \mapsto n]\right)
$$

Consider the cases for the derivation of $\langle e, \sigma\rangle \longrightarrow\left\langle e^{\prime}, \sigma^{\prime}\right\rangle$.

- Case ADD. This is an axiom. Here, $e \equiv n+m$ and $e^{\prime}=p$ where $p$ is the sum of $m$ and $n$, and $\sigma^{\prime}=\sigma$. The result holds immediately.
- Case LADD. This is an inductive case. Here, $e \equiv e_{1}+e_{2}$ and $e^{\prime} \equiv e_{1}^{\prime}+e_{2}$ and $\left\langle e_{1}, \sigma\right\rangle \longrightarrow\left\langle e_{1}^{\prime}, \sigma^{\prime}\right\rangle$. By the inductive hypothesis, applied to $\left\langle e_{1}, \sigma\right\rangle \longrightarrow\left\langle e_{1}^{\prime}, \sigma^{\prime}\right\rangle$, we have that either $\sigma=\sigma^{\prime}$ or there is some variable $x$ and integer $n$ such that $\sigma^{\prime}=\sigma[x \mapsto n]$, as required.
- Case AsG. This is an axiom. Here $e \equiv x:=n ; e_{2}$ and $e^{\prime} \equiv e_{2}$ and $\sigma^{\prime}=\sigma[x \mapsto n]$. The result holds immediately.
- We leave the other cases (VAR, RADD, LMUL, RMUL, MUL, and ASG1) as exercises for the reader. Seriously, try them. Make sure you can do them. Go on, you're reading these notes, you may as well try the exercise.
