

# Lambda Calculus

CS 1520 (Spring 2025)

Harvard University

Tuesday, February 18, 2025

# Today, we will learn about

- ▶ Lambda calculus
- ▶  $\alpha$ -equivalence
- ▶  $\beta$ -reduction
- ▶ Call-by-value semantics
- ▶ Call-by-name semantics

# $\lambda$ -calculus

- universal model of computation
- $e := x$                     *// variable*
  - |  $\lambda x.e$                     *// function abstraction*
  - |  $e e$                         *// function application*

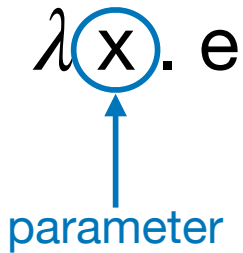

$\lambda x . e$

function

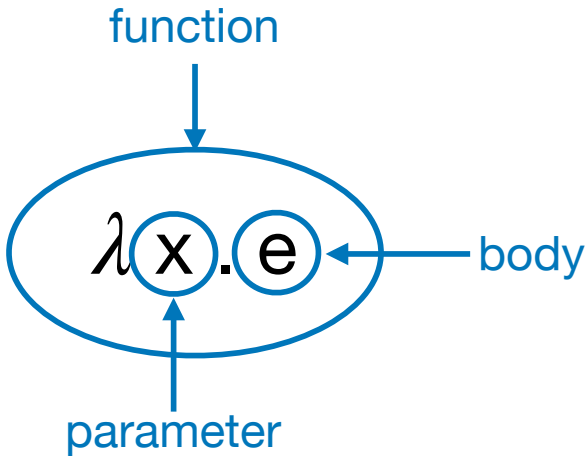

$\lambda x . e$

$\lambda$   $x$  . e

parameter

$\lambda x . \textcircled{e}$  ← body

# Lambda calculus: Intuition

A function is a rule for determining a value from an argument. Some examples of functions in mathematics are

$$f(x) = x^3$$

$$g(y) = y^3 - 2y^2 + 5y - 6.$$

# Lambda calculus: Intuition

A function is a rule for determining a value from an argument. Some examples of functions in mathematics are

$$f = \lambda x.x^3$$

$$g = \lambda y.y^3 - 2y^2 + 5y - 6.$$

# Pure vs Applied Lambda Calculus

- ▶ The pure  $\lambda$ -calculus contains just function definitions (called *abstractions*), variables, and function *applications*.
- ▶ If we add additional data types and operations (such as integers and addition), we have an *applied*  $\lambda$ -calculus.

# Pure Lambda Calculus: Syntax

$e ::= x$

variable

|  $\lambda x. e$

abstraction

|  $e_1 e_2$

application

# Abstractions

# Abstractions

- ▶ An abstraction  $\lambda x. e$  is a function
- ▶ Variable  $x$  is the *parameter*
- ▶ Expression  $e$  is the *body* of the function.
- ▶ The expression  $\lambda y. y \times y$  is a function that takes an argument  $y$  and returns square of  $y$ .

# Applications

- ▶ An application  $e_1 e_2$  requires that  $e_1$  is (or evaluates to) a function, and then applies the function to the expression  $e_2$ .
- ▶ For example,  $(\lambda y. y \times y) 5$  is 25

# Examples

- $\lambda x. x$  a lambda abstraction called the *identity function*
- $\lambda x. (f (g x))$  another abstraction
- $(\lambda x. x) 42$  an application
- $\lambda y. \lambda x. x$  an abstraction, ignores its argument  
and returns the identity function

Lambda expressions extend as far to the right as possible

$\lambda x. x \lambda y. y$  is the same as  $\lambda x. (x (\lambda y. y))$ , and is not the same as  $(\lambda x. x) (\lambda y. y)$ .

# Application is left-associative

$e_1 e_2 e_3$  is the same as  $(e_1 e_2) e_3$ .

# Use parentheses!

In general, use parentheses to make the parsing of a lambda expression clear if you are in doubt.

# Variable binding

- ▶ An occurrence of a variable  $x$  in a term is bound if there is an enclosing  $\lambda x. e$ ; otherwise, it is *free*.
- ▶ A *closed term* is one in which all identifiers are bound.

Variable binding:  $\lambda x. (x (\lambda y. y a) x) y$

# Variable binding: $\lambda x. (x (\lambda y. y a) x) y$

- ▶ Both occurrences of  $x$  are bound
- ▶ The first occurrence of  $y$  is bound
- ▶ The  $a$  is free
- ▶ The last  $y$  is also free, since it is outside the scope of the  $\lambda y$ .

# Binding operator

The symbol  $\lambda$  is a *binding operator*: variable  $x$  is bound in  $e$  in the expression  $\lambda x. e$ .

# $\alpha$ -equivalence

- ▶  $\lambda x. x$  is the same function as  $\lambda y. y$ .
- ▶ Expressions  $e_1$  and  $e_2$  that differ only in the name of bound variables are called  *$\alpha$ -equivalent* (“alpha equivalent”)
- ▶ Sometimes written  $e_1 =_{\alpha} e_2$ .

## Quiz: $\alpha$ -equivalence

- ▶ Are  $\lambda x. \lambda y. x y$  and  $\lambda y. \lambda x. y x$   $\alpha$ -equivalent?

# Higher-order functions

- ▶ In lambda calculus, functions are values.
- ▶ In the pure lambda calculus, every value is a function, and every result is a function!

# Higher-order functions

$\lambda f. f\ 42$

# Higher-order functions

$$\lambda v. \lambda f. (f v)$$

Takes an argument  $v$  and returns a function that applies its own argument (a function) to  $v$ .

# Semantics

# $\beta$ -equivalence

- ▶ We would like to regard  $(\lambda x. e_1) e_2$  as equivalent to  $e_1$  where every (free) occurrence of  $x$  is replaced with  $e_2$ .
- ▶ E.g. we would like to regard  $(\lambda y. y \times y) 5$  as equivalent to  $5 \times 5$ .

# Substitution $e_1\{e_2/x\}$

- ▶ We write  $e_1\{e_2/x\}$  to mean expression  $e_1$  with all free occurrences of  $x$  replaced with  $e_2$ .
- ▶ We call  $(\lambda x. e_1) e_2$  and  $e_1\{e_2/x\}$   *$\beta$ -equivalent*.
- ▶ Rewriting  $(\lambda x. e_1) e_2$  into  $e_1\{e_2/x\}$  is called a  *$\beta$ -reduction*.
- ▶ This corresponds to executing a lambda calculus expression.

# Different semantics for the lambda calculus

$$(\lambda x. x + x) ((\lambda y. y) 5)$$

# Different semantics for the lambda calculus

$$(\lambda x. x + x) ((\lambda y. y) 5)$$

We could use  $\beta$ -reduction to get either  $((\lambda y. y) 5) + ((\lambda y. y) 5)$  or  $(\lambda x. x + x) 5$ .

# Evaluation strategies: Full $\beta$ -reduction

Allows  $(\lambda x. e_1) e_2$  to step to  $e_1\{e_2/x\}$  at any time.

# Full $\beta$ -reduction: small-step operational semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e_1) e_2 \longrightarrow e_1\{e_2/x\}}$$

# Full $\beta$ -reduction: small-step operational semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e_1) e_2 \longrightarrow e_1\{e_2/x\}}$$

$$\frac{e_1 \longrightarrow e'_1}{e_1 e_2 \longrightarrow e'_1 e_2}$$

# Full $\beta$ -reduction: small-step operational semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e_1) e_2 \longrightarrow e_1\{e_2/x\}}$$

$$\frac{e_1 \longrightarrow e'_1}{e_1 e_2 \longrightarrow e'_1 e_2}$$

$$\frac{e_2 \longrightarrow e'_2}{e_1 e_2 \longrightarrow e_1 e'_2}$$

# Full $\beta$ -reduction: small-step operational semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e_1) e_2 \longrightarrow e_1\{e_2/x\}}$$

$$\frac{e_1 \longrightarrow e'_1}{e_1 e_2 \longrightarrow e'_1 e_2}$$

$$\frac{e_2 \longrightarrow e'_2}{e_1 e_2 \longrightarrow e_1 e'_2}$$

$$\frac{e \longrightarrow e'}{\lambda x. e \longrightarrow \lambda x. e'}$$

# Normal form

A term  $e$  is said to be in *normal form* when there is no  $e'$  such that  $e \longrightarrow e'$ .

Not every term has a normal form under full  $\beta$ -reduction.

Consider  $\Omega = (\lambda x. x x) (\lambda x. x x)$ .

$$\Omega = (\lambda x. x x) (\lambda x. x x) \longrightarrow (\lambda x. x x) (\lambda x. x x) = \Omega$$

It's an infinite loop!

# Well-behaved nondeterminism

$$(\lambda x. \lambda y. y) \Omega (\lambda z. z)$$

# Well-behaved nondeterminism

$$(\lambda x. \lambda y. y) \Omega (\lambda z. z)$$

This term has two redexes in it, the one with abstraction  $\lambda x$ , and the one inside  $\Omega$ .

# Well-behaved nondeterminism

- ▶ The full  $\beta$ -reduction strategy is non-deterministic.
- ▶ When a term has a normal form, however, it never has more than one.

# Full $\beta$ -reduction is confluent

## Theorem (Confluence)

*If  $e \longrightarrow^* e_1$  and  $e \longrightarrow^* e_2$  then there exists  $e'$  such that  $e_1 \longrightarrow^* e'$  and  $e_2 \longrightarrow^* e'$ .*

# Full $\beta$ -reduction is confluent

## Corollary

*If  $e \longrightarrow^* e_1$  and  $e \longrightarrow^* e_2$  and both  $e_1$  and  $e_2$  are in normal form, then  $e_1 = e_2$ .*

## Proof.

An easy consequence of confluence. □

# Normal Order Evaluation

- ▶ *Normal order evaluation* uses the full  $\beta$ -reduction rules, except the left-most redex is always reduced first.
- ▶ Will eventually yield the normal form, if one exists.
- ▶ Allows reducing redexes inside abstractions

# Call-by-value

- ▶ *Call-by-value* only allows an application to reduce after its argument has been reduced to a value and does not allow evaluation under a  $\lambda$ .
- ▶ Given an application  $(\lambda x. e_1) e_2$ , CBV semantics makes sure that  $e_2$  is a value before calling the function.
- ▶ A value is an expression that can not be reduced/executed/simplified any further.

# CBV: Small step operational semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e) v \longrightarrow e\{v/x\}}$$

# CBV: Small step operational semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e) v \longrightarrow e\{v/x\}}$$

$$\frac{e_1 \longrightarrow e'_1}{e_1 e_2 \longrightarrow e'_1 e_2}$$

# CBV: Small step operational semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e) v \longrightarrow e\{v/x\}}$$

$$\frac{e_1 \longrightarrow e'_1}{e_1 e_2 \longrightarrow e'_1 e_2}$$

$$\frac{e \longrightarrow e'}{v e \longrightarrow v e'}$$

# CBV: Examples

$$\begin{aligned}(\lambda x. \lambda y. y x) (5 + 2) \lambda x. x + 1 &\longrightarrow (\lambda x. \lambda y. y x) 7 \lambda x. x + 1 \\ &\longrightarrow (\lambda y. y 7) \lambda x. x + 1 \\ &\longrightarrow (\lambda x. x + 1) 7 \\ &\longrightarrow 7 + 1 \\ &\longrightarrow 8\end{aligned}$$

$$\begin{aligned}(\lambda f. f 7) ((\lambda x. x x) \lambda y. y) &\longrightarrow (\lambda f. f 7) ((\lambda y. y) (\lambda y. y)) \\ &\longrightarrow (\lambda f. f 7) (\lambda y. y) \\ &\longrightarrow (\lambda y. y) 7 \\ &\longrightarrow 7\end{aligned}$$

# Call-by-name semantics

- ▶ Applies the function as soon as possible.
- ▶ No need to ensure that the expression to which a function is applied is a value.

# Call-by-name semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e_1) e_2 \longrightarrow e_1\{e_2/x\}}$$

# Call-by-name semantics

$$\beta\text{-REDUCTION} \frac{}{(\lambda x. e_1) e_2 \longrightarrow e_1\{e_2/x\}}$$

$$\frac{e_1 \longrightarrow e'_1}{e_1 e_2 \longrightarrow e'_1 e_2}$$

# Call-by-name semantics: example

$$\begin{aligned}(\lambda x. \lambda y. y x) (5 + 2) \lambda x. x + 1 &\longrightarrow (\lambda y. y (5 + 2)) \lambda x. x + 1 \\ &\longrightarrow (\lambda x. x + 1) (5 + 2) \\ &\longrightarrow (5 + 2) + 1 \\ &\longrightarrow 7 + 1 \\ &\longrightarrow 8\end{aligned}$$

compare to CBV:

$$\begin{aligned}(\lambda x. \lambda y. y x) (5 + 2) \lambda x. x + 1 &\longrightarrow (\lambda x. \lambda y. y x) 7 \lambda x. x + 1 \\ &\longrightarrow (\lambda y. y 7) \lambda x. x + 1 \\ &\longrightarrow (\lambda x. x + 1) 7 \\ &\longrightarrow 7 + 1 \\ &\longrightarrow 8\end{aligned}$$

# Call-by-name semantics: example

$$\begin{aligned}(\lambda f. f\ 7)\ ((\lambda x. x\ x)\ \lambda y. y) &\longrightarrow ((\lambda x. x\ x)\ \lambda y. y)\ 7 \\ &\longrightarrow ((\lambda y. y)\ (\lambda y. y))\ 7 \\ &\longrightarrow (\lambda y. y)\ 7 \\ &\longrightarrow 7\end{aligned}$$

compare to CBV:

$$\begin{aligned}(\lambda f. f\ 7)\ ((\lambda x. x\ x)\ \lambda y. y) &\longrightarrow (\lambda f. f\ 7)\ ((\lambda y. y)\ (\lambda y. y)) \\ &\longrightarrow (\lambda f. f\ 7)\ (\lambda y. y) \\ &\longrightarrow (\lambda y. y)\ 7 \\ &\longrightarrow 7\end{aligned}$$

# CBV vs CBN

One way in which CBV and CBN differ is when arguments to functions have no normal forms.

$$(\lambda x. (\lambda y. y)) \Omega$$

Under CBV semantics, this term does not have a normal form. If we use CBN semantics, then we have

$$(\lambda x. (\lambda y. y)) \Omega \longrightarrow_{\text{CBN}} \lambda y. y$$

# CBV and CBN

- ▶ CBV and CBN are common evaluation orders
- ▶ Many programming languages use CBV semantics
- ▶ “Lazy” languages, such as Haskell, typically use Call-by-need semantics, a more efficient semantics similar to Call-by-name in that it does not evaluate actual arguments unless necessary
- ▶ However, Call-by-value semantics ensures that arguments are evaluated at most once.

# Break

- ▶ If possible, give a program that cannot reduce in CBN and CBV, but reduces in full  $\beta$ -reduction.
- ▶ If possible, give a program that steps to the same expression in CBN and CBV.
- ▶ Formulate the rules of CBV in big-step style.
- ▶ How would you create a let-binding in lambda calculus?
- ▶ How do we define  $e_1\{e_2/x\}$  formally?

# CBV in big-step

$$\frac{}{\lambda x. e \Downarrow \lambda x. e}$$

$$\frac{e_1 \Downarrow \lambda x. e_{12} \quad e_2 \Downarrow v_2 \quad e_{12}\{v_2/x\} \Downarrow v}{e_1 e_2 \Downarrow v}$$

# $e_1\{e_2/x\}$ formally

$$x\{e/x\} = e$$

$$y\{e/x\} = y$$

if  $y \neq x$

$$(\lambda y. e_1)\{e/x\} = \lambda y. (e_1\{e/x\})$$

if  $y \neq x$  and  $y \notin FV(e)$

$$(e_1 e_2)\{e/x\} = (e_1\{e/x\}) (e_2\{e/x\})$$

# $e_1\{e_2/x\}$ (almost) formally

$$x\{e/x\} = e$$

$$y\{e/x\} = y$$

if  $y \neq x$

$$(\lambda y. e_1)\{e/x\} = \lambda y. (e_1\{e/x\})$$

if  $y \neq x$  and  $y \notin FV(e)$

$$(e_1 e_2)\{e/x\} = (e_1\{e/x\}) (e_2\{e/x\})$$

# Rules

- $\alpha$ -conversion

$$\lambda x.e[x] \rightarrow \lambda y.e[y]$$

- $\beta$ -reduction

$$(\lambda x.e_1) e_2 \rightarrow e_1\{e_2/x\}$$

- $\eta$ -conversion

$$(\lambda x.e x) \rightarrow e \text{ if } x \text{ does not occur free in } e$$

# Rules

- $\alpha$ -conversion

$$\lambda x.e[x] \rightarrow \lambda y.e[y]$$

- $\beta$ -reduction

$$(\lambda x.e1) e2 \rightarrow e1\{e2/x\}$$

- $\eta$ -conversion

$$(\lambda x.e x) \rightarrow e \text{ if } x \text{ does not occur free in } e$$

# Rules

- $\alpha$ -conversion  
 $\lambda x.e[x] \rightarrow \lambda y.e[y]$

- $\beta$ -reduction  
 $(\lambda x.e1) e2 \rightarrow e1\{e2/x\}$

- $\eta$ -conversion  
 $(\lambda x.e x) \rightarrow e$  if  $x$  does not occur free in  $e$

# $\beta$ -reduction

# $\beta$ -reduction

$$(\lambda x. e1) e2 \rightarrow e1\{e2/x\}$$

# $\beta$ -reduction

The diagram illustrates the beta-reduction rule. On the left, the expression  $(\lambda x. e1) e2$  is enclosed in a blue oval. A blue arrow points upwards from the text  $\beta$ -redex below to the bottom of the oval. To the right of the oval is a right-pointing arrow  $\rightarrow$ , followed by the expression  $e1\{e2/x\}$ .

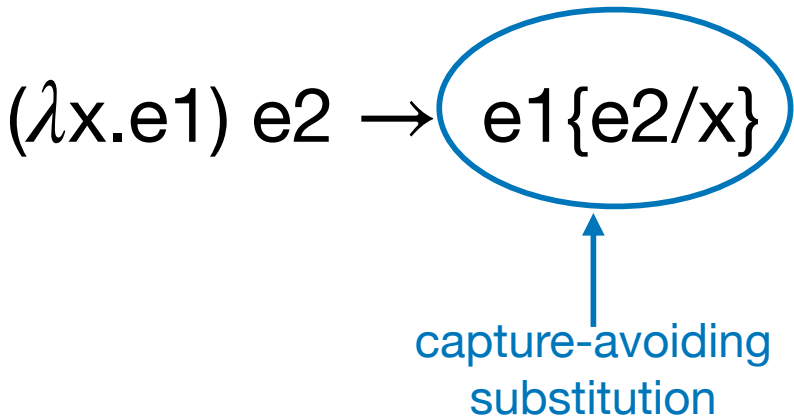

$$(\lambda x. e1) e2 \rightarrow e1\{e2/x\}$$

$\beta$ -redex

# $\beta$ -reduction

$$(\lambda x. e1) e2 \rightarrow e1\{e2/x\}$$
